- Field measurements and simulations
- Results
- Conclusion

Introduction

Brazil has one of most important crop producers of world:

- 48,8 millions hectares of area cultivated;
- Production: 187 millions of grain.

(IBGE, 2013)

Machinery harvesters before harvest soybean farm in Tangara da Serra, in Cuiabá (Andre Penner / AP)

Introduction (cont.)

- **NO emissions** remain poorly characterized for many practices and many regions of world, including Brazil;
- Mathematical models can help fill these data gaps but most models have not been widely validated in several ecosystems and agricultural systems;
- Li, C. (2000) is a validation study comparing NO emissions from DNDC predictions against experimental measurement.

Li, C., 2000. Modeling trace gas emissions from agricultural ecosystems. *Nutrient Cycling in Agroecosystems* 58, 259–276.

Introduction (cont.)

- **But**, there is few studies about NO emissions from cover crop management system.
- **Objective in this research** is to assess the ability of DNDC model for predicting NO emissions from cover crop management in the Brazilian *Cerrado*.

Site description

- **Experiment at Embrapa Cerrado:** Mar-2002 To Jun- 2003
- **Experimental design:** randomized block design, with three replications and split plot.
- **Soils:** clay
- **Soil Organic Carbon (SOC):** 23.6 g .kg⁻¹
- **Bulk density (BD):** 0.85 g cm⁻³
- **pH 6.2 (CaCl₂)**
- **Mean annual rainfall:** 797 mm
- **Mean Air temperature:** 23°C

Field measurements and simulations

Observed data:

➤ NO flux was measured with use of dynamic chamber technical combined with chemiluminescence analyzer and data logger.

Predicted data:

➤ Observed flux data , local climate, soil and management information were utilized to test DNDC95 version its applicability for cover crop management in Conventional and No-Tillage System for:

- *Crotalaria juncea*;
- *Mucuna pruriense*;
- Natural fallow.

e Abastecimento

Results

For cover crop in Conventional Systems:

➤ Predicted emissions were very similar to the collected data with mean, 0.8 kg NO-N. ha⁻¹ yr⁻¹, T test = 0,69

For cover crop in No-tillage Systems:

➤ Predicted emissions were mean, 0.7 kg NO-N ha⁻¹ yr⁻¹, lower than collected data for *Mucuna pruriense* (mean, 1.3 kg NO-N ha⁻¹ yr⁻¹)

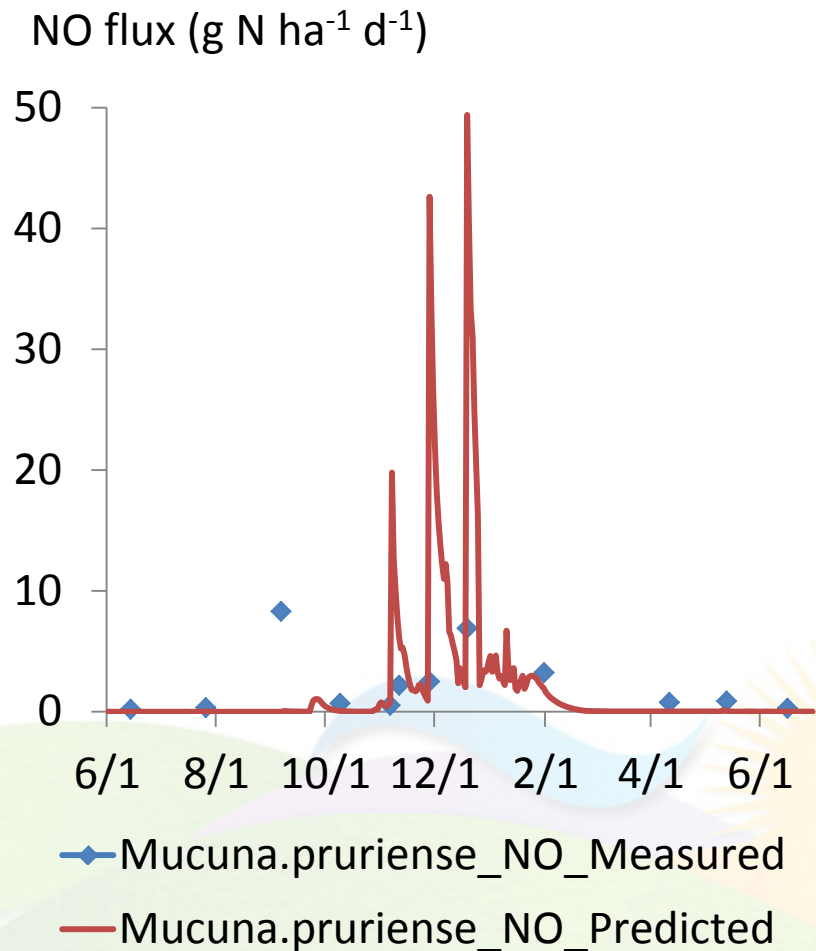

➤ Predicted emissions from *Crotalaria juncea* and *Mucuna pruriense* both were higher than emissions from natural fallow (mean, 0.59 kg NO-N .ha⁻¹ yr⁻¹)

Agricultura, Pecuária
e Abastecimento

Conclusion

- Results reveal that the DNDC model yet requires calibration for application in no-tillage systems cultivated in Brazilian *Cerrado*.
